

# SPECTACLED THRUSH

*Turdus nudigenis*

Spectacled thrushes are grey-brown which helps them blend in, but have a patch of bright yellow skin around their eye which is where they get their name

Spectacled thrushes are found in parts of South America including Columbia, Brazil and Venezuela, and in Trinidad and Tobago

Spectacled thrushes eat a variety of fruits, berries and insects. Young hatchlings are fed worms which are a good source of protein

These thrushes make their nests in the crooks of tree branches using mud, twigs and other plant materials and females lay 2-4 bluish-green eggs with reddish speckles 1-2 times a year
